Project abstract:

Data quality is one of the highest priorities for Global Biodiversity Information Facility (GBIF), the national nodes and other providers, depends on both automatic methods and community experts to detect and correct data issues. Not all issues can however be automatically detected or corrected, so community assistance is needed to help improve the quality of exposed biological data. Semantic Web is a new approach where conventional web documents can be extended with additional data that add meaning to them rather than structure alone. On the Semantic Web, data can be retrieved from seemingly unrelated fields automatically in order to combine them, find relations, and make discoveries. The research proposal aims to use Semantic Web technologies to convert datasets published in GBIF to Linked Open Data (LOD) in order to perform quality controls in an automated way and promote the integration of information with other datasets relevant for Biodiversity.

Applying Linked Data and Semantic Web Standards to Improving Interoperability of GBIF Datasets

Data Collection

The primary data that will be used come from Darwin Core files (DwC-a) published through the institutional IPT belonging to the National Patagonian Center (CENPAT-CONICET) <http://ipt.cenpat-conicet.gob.ar:8081/>.

Notes:

Darwin Core Archive (DwC-A) is a biodiversity informatics data standard that makes use of the Darwin Core terms to produce a single, self contained dataset for sharing species-level (taxonomic), species-occurrence data, and sampling-event data. An archive is a set of text files, in standard comma- or tab-delimited format, with a simple descriptor file (called *meta.xml*) to inform others how your files are organised. The format is defined in the [Darwin Core Text Guidelines](#). *It is the preferred format for publishing data in the GBIF network.*

The data is collected by our samples or observations of marine and terrestrial species, and then digitized using the tools provided by GBIF to create the DwC-A files

Documentation and Metadata

The preferred format for publishing data to the GBIF network is the [Darwin Core](#) Archive, and its Integrated Publishing Toolkit uses [EML](#) as its metadata standard.

Ethics and Legal Compliance

Question not answered.

Question not answered.

Storage and Backup

Qualitative data will be backed up and secured by the lead country researcher on a regular basis and metadata will include clear labelling of versions and dates. There are some potential sensitivities around some of the data being collected, so the project will establish a system for protecting data while it is being processed, including use of passwords and safe back-up hardware.

The primary data after the conversion, is stored in GraphDB triplestore, accessible publicly from <http://web.cenpat-conicet.gob.ar:7200/>. This server makes copies daily.

GraphDB manages the users and the privileges that each user has to access the repository. In case of possible unauthorized users, graphDB controls and reports this situation to the administrator.

Selection and Preservation

In this research, because it is primary biodiversity data that can be used in various analyzes, it is important that the primary data and metadata are

persistent for several years.

Data will be kept for at least 10 years. After this time the data may be subject to deletion if it has not been reused, accessed, or cited.

Data Sharing

The most appropriate means of sharing the data generated through the project will be online, through institutional websites. The project will have a dedicated space on the CENPAT institutional website to facilitate this, and all other involved institutions will also be encouraged to host the data on their websites.

Linked Open Data is available for access through GraphDB <http://web.cenpat-conicet.gob.ar:7200/>, it can be downloaded as data dump or accessed through the SPARQL end point.
